**Introduction:** Because of the Korean Network for Organ Sharing (KONOS) guidelines, brain-dead donor transplantation (liver/kidney) from Hepatitis B or C (+) donors only can be done to the same hepatitis (+) recipients. In the US, organ transplantation from hepatitis (+) donors to (-) recipients has been implemented for more than 15 years. We need to consider the safety of transplantation from hepatitis B or C (+) donors to hepatitis(-) recipients. The aim of the study is to show the transplantation results from hepatitis B or C (+) donors to each hepatitis(-) recipient and make it as a starting point for the consideration.

**Methods:** This is a retrospective, observational study using data from Korean Organ Transplantation Registry Data Analysis (KOTRY). A total of 2105 kidney transplantations from brain-dead donors, from January 2015 to June 2020 were included in this study. It consists of 80 HBV(+) grafts, 12 HCV(+) grafts and 2013 hepatitis(-) grafts.

**Results:** In donor characteristics, median ages of the 3 groups (HBV(+), HCV(+), hepatitis(-)) were 57.4+-10.1, 50.1+-11.8 and 48.7+-14.9, respectively (p=0.02, HCV(+)-hepatitis(-) p=0.04). Baseline serum creatinine (median, mg/dL) were 1.25+-0.87, 1.45+-0.46 and 1.57+-1.34, respectively (p=0.02, HBV(+)-hepatitis(-) p=0.01). In recipient characteristics, Male/Female ratio were 60/20, 7/5 and 1228/785, respectively (p=0.04, HBV(+)-hepatitis(-) p=0.04). Wait time (median, days) were 1550.8+-1145.5, 1434.3+-957.2 and 2188+-1207.9, respectively (p<0.001, HBV(+)-hepatitis(-) p<0.001). In post-transplant results, there were no significant differences in follow-up serum creatinine, survival, postop hospital day and complication between the 3 groups. From a Kaplan-Meier analysis, overall patient survival rates after KT at 5 years were 95%, 100% and 76.2%, respectively (HBV(+)-hepatitis(-) p<0.001). Overall graft survival rates after KT at 5 years were 95%, 83.3% and 84.5%, respectively (HBV(+)-hepatitis(-) p=0.02).

**Conclusion:** There were no differences in baseline, postop and follow-up serum creatinine between the 3 groups. Moreover, 5-year patient and graft survival were significantly higher in HBV(+) grafts than in hepatitis(-) grafts. Do not hesitate to consider implementing brain-dead donor transplantation from hepatitis(+) donors to hepatitis(-) recipients.
